Abstract

We give a detailed account of the derivation of a master equation for two coupled cavities in the presence of dissipation. The analytical solution is presented and physical limits of interest are discussed. Firstly we show that the decay rate of initial coherent states can be significantly modified if the two cavities have different decay rates and are weakly coupled through a wire. Moreover, we show that also decoherence rates can be substantially altered by manipulation of physical parameters. Conditions for experimental realizations are discussed.

1 Introduction

The past decade can celebrate having overcome several barriers, the most important of them being the objections commonly levelled against the idea of the observability of large scale quantum phenomena. The amazing technological developments in several areas of physics allowed for the experimental verification of essentially quantum effects like tunneling, various kinds of interference and entanglement phenomena in mesoscopic physics. So we have

reached the point where we need to know rather urgently what are the mechanisms which cause decoherence, particularly at the mesoscopic scale, since controlling such mechanism has immediate and profound technological consequences, besides its value for the fundamentals of Quantum Mechanics and the (unsolved) problem of the classical limit.

Modern cavity quantum electrodynamics (cavity QED) sheds light onto the most fundamental aspects of coherence and decoherence in quantum mechanics. One of the main advantages of such experiments is that they can be described by elementary models, being at the same time rich enough to reveal intriguing subtleties of the interplay of coherent dynamics with external coupling. It represents therefore a unique paradigm for matching theory with experiment in the study of quantum coherence. In particular a very important experiment has been proposed [1] and realized [2] where one monitors the coherence loss of a superposition state.

The predominant component of decoherence in cavity QED systems corresponds simply to the escape or emission of photons, either by absorption into the cavity walls or by scattering or transmission into electromagnetic modes outside the cavity. This decoherence mechanism fits well into the scheme of coupling to extended modes. The description of decoherence through a linear coupling to a set of harmonic oscillators seems to work well, both qualitatively and quantitatively.

The purpose of the present work is to investigate dissipation and decoherence effects on two field modes by generalizing the usual dissipation mechanism for the present situation. The results can be experimentally implemented in two distinct ways: in a regime with two modes of one cavity close to resonance with an atomic transition, a task already implemented [3], and in an experiment involving two cavities, as the one proposed in ref. [4], or in the teleportation scheme [5].

Our results show interesting physical effects for the situation when the coupling of each mode with the reservoir is not independent. Despite of being of difficult experimental implementation, we show which are the key parameters or combinations of parameters which can lead to a decoherence free subspace, or, more modestly, to decoherence control.

Moreover we investigate the coupling of two cavities through a wire and show how dissipation can be controlled if the cavities are initially fed with coherent states.

The counterintuitive effects here presented are consequences of quantum destructive interference of coupling constants, a well studied theoretical prevision [6] with interesting consequences as electromagnetically induced transparency (EIT) [7], lasing without inversion [8] and narrowing of spectral lines [9,10].

The paper is organized as follows. In section II we derive the master equation from a Hamiltonian for two coupled oscillators in the presence of an environment, under some dynamical hypothesis. Section III presents the exact formal solution of the Liouvillian by means of Lie-algebraic techniques. There we discuss conditions for dissipation control. In section IV we analyse the case with initially coherent states in the cavities and present an interesting effect in the case of weak coupling between them. Section V discusses the conditions for decoherence control through the study of an initially pure entangled state. In section VI we comment on the (difficult) experimental realization of the conditions found in the previous sections.

2 Master equation derivation

We consider two modes linearly coupled both to each other and to the environment. In both cases applying the Rotating Wave Approximation (RWA), what is not too restrictive in the microwave domain [11]. This corresponds to the Hamiltonian

$$\begin{aligned}
\mathbf{H}_o &= \mathbf{H}_S + \mathbf{H}_R, \\
\mathbf{H}_S &= \hbar\omega_a \mathbf{a}^\dagger \mathbf{a} + \hbar\omega_b \mathbf{b}^\dagger \mathbf{b} + \hbar g (\mathbf{a}^\dagger \mathbf{b} + \mathbf{b}^\dagger \mathbf{a}), \\
\mathbf{H}_E &= \sum_k \hbar\omega_k \mathbf{c}_k^\dagger \mathbf{c}_k, \\
\mathbf{H}_{int} &= \sum_k \hbar (\alpha_k \mathbf{c}_k^\dagger \mathbf{a} + \alpha_k^* \mathbf{a}^\dagger \mathbf{c}_k) + \sum_k \hbar (\beta_k \mathbf{c}_k^\dagger \mathbf{b} + \beta_k^* \mathbf{b}^\dagger \mathbf{c}_k),
\end{aligned} \tag{1}$$

where the operators $\mathbf{a}$ ($\mathbf{b}$) and $\mathbf{a}^\dagger$ ($\mathbf{b}^\dagger$) are annihilation and creation operators of the field mode A (B), directly coupled by the last term in eq. (1), where g is a real positive coupling constant. The environment is modelled, as usual, by a set of harmonic oscillators with creation and annihilation operators $\mathbf{c}_k^\dagger$ and $\mathbf{c}_k$, with complex coupling constants α_k (β_k) to the mode a (b). Much of the results to be presented will depend on the existence of correlations between α_k and β_k for fixed k , as must become clear later on.

It is convenient to work with the normal modes of $\mathbf{H}_S$:

$$\begin{aligned}
\mathbf{H}_S &= \hbar\omega_1 \mathbf{a}_1^\dagger \mathbf{a}_1 + \hbar\omega_2 \mathbf{a}_2^\dagger \mathbf{a}_2, \\
\mathbf{H}_{int} &= \sum_{i=1}^2 \sum_k \hbar (\alpha_{ik} \mathbf{c}_k^\dagger \mathbf{a}_i + \alpha_{ik}^* \mathbf{a}_i^\dagger \mathbf{c}_k),
\end{aligned} \tag{2}$$

where

$$\begin{aligned}
\omega_1 &= \frac{(\omega_a + \omega_b) + \sqrt{(\omega_a - \omega_b)^2 + 4g^2}}{2}, & \omega_2 &= \frac{(\omega_a + \omega_b) - \sqrt{(\omega_a - \omega_b)^2 + 4g^2}}{2}, \\
\alpha_{1k} &= \alpha_k \cos \theta + \beta_k \sin \theta, & \alpha_{2k} &= -\alpha_k \sin \theta + \beta_k \cos \theta, \\
\mathbf{a}_1 &= \mathbf{a} \cos \theta + \mathbf{b} \sin \theta, & \mathbf{a}_2 &= -\mathbf{a} \sin \theta + \mathbf{b} \cos \theta, \\
\cos \theta &= \sqrt{\frac{1}{2} \left(1 + \frac{\omega_a - \omega_b}{\sqrt{(\omega_a - \omega_b)^2 + 4g^2}} \right)}, & \sin \theta &= \sqrt{\frac{1}{2} \left(1 - \frac{\omega_a - \omega_b}{\sqrt{(\omega_a - \omega_b)^2 + 4g^2}} \right)}.
\end{aligned}$$

The operators $\mathbf{a}_i$ and $\mathbf{a}_i^\dagger$ obey the usual commutation relations for bosons.

Time evolution of the complete density operator ρ is given by von Neumann equation

$$\frac{d}{dt} \tilde{\rho}(t) = \frac{-i}{\hbar} [\tilde{\mathbf{H}}_{int}(t), \tilde{\rho}(t)], \quad (4)$$

where the tilde over the operators tells us that they are written in the interaction picture,

$$\tilde{\mathbf{O}} = \exp \left\{ \frac{i}{\hbar} \mathbf{H}_o t \right\} \mathbf{O} \exp \left\{ \frac{-i}{\hbar} \mathbf{H}_o t \right\}. \quad (5)$$

Integrating eq. (4) and iterating twice leads to

$$\tilde{\rho}(t) - \tilde{\rho}(0) = -\frac{i}{\hbar} \int_0^t dt' [\tilde{\mathbf{H}}_{int}(t'), \tilde{\rho}(0)] - \frac{1}{\hbar^2} \int_0^t dt' \int_0^{t'} dt'' [\tilde{\mathbf{H}}_{int}(t'), [\tilde{\mathbf{H}}_{int}(t''), \tilde{\rho}(0)]] + \mathcal{O}^3(\tilde{\mathbf{H}}_{int}). \quad (6)$$

Since the high quality factor of the cavity(ies), we consider weak coupling of modes A and B to the environment, which allow us to disregard the terms of third order in $\tilde{\mathbf{H}}_{int}$, denoted $\mathcal{O}^3(\tilde{\mathbf{H}}_{int})$, in the following calculation.

Taking the trace over the environment degrees of freedom gives the corresponding equation for the reduced density operator for the subsystem composed by the two relevant modes (this subsystem will be called *system*) and eq. (6) then implies

$$\tilde{\rho}_S(t) - \tilde{\rho}_S(0) = -i \int_0^t dt' \text{Tr}_E \sum_{i=1}^2 [\mathbf{\Gamma}_i^\dagger(t') \tilde{\mathbf{a}}_i(t') + \mathbf{\Gamma}_i(t') \tilde{\mathbf{a}}_i^\dagger(t'), \tilde{\rho}(0)]$$

$$-\int_0^t dt' \int_0^{t'} dt'' \text{Tr}_E \left\{ \sum_{i,j=1}^2 \left[\begin{aligned} &+ \left(\begin{aligned} &\Gamma_i^\dagger(t') \Gamma_j^\dagger(t'') \tilde{\mathbf{a}}_i(t') \tilde{\mathbf{a}}_j(t'') \tilde{\rho}(0) + \text{h.c.} \\ &+ \Gamma_i(t') \Gamma_j^\dagger(t'') \tilde{\mathbf{a}}_i^\dagger(t') \tilde{\mathbf{a}}_j(t'') \tilde{\rho}(0) + \text{h.c.} \end{aligned} \right) \\ &+ \left(\begin{aligned} &\Gamma_i^\dagger(t') \Gamma_j(t'') \tilde{\mathbf{a}}_i(t') \tilde{\mathbf{a}}_j^\dagger(t'') \tilde{\rho}(0) + \text{h.c.} \\ &+ \Gamma_i(t') \Gamma_j(t'') \tilde{\mathbf{a}}_i^\dagger(t') \tilde{\mathbf{a}}_j^\dagger(t'') \tilde{\rho}(0) + \text{h.c.} \end{aligned} \right) \\ &- \left(\begin{aligned} &\Gamma_i^\dagger(t') \tilde{\mathbf{a}}_i(t') \tilde{\rho}(0) \Gamma_j^\dagger(t'') \tilde{\mathbf{a}}_j(t'') + \text{h.c.} \\ &+ \Gamma_i(t') \tilde{\mathbf{a}}_i^\dagger(t') \tilde{\rho}(0) \Gamma_j^\dagger(t'') \tilde{\mathbf{a}}_j(t'') + \text{h.c.} \end{aligned} \right) \\ &- \left(\begin{aligned} &\Gamma_i^\dagger(t') \tilde{\mathbf{a}}_i(t') \tilde{\rho}(0) \Gamma_j(t'') \tilde{\mathbf{a}}_j^\dagger(t'') + \text{h.c.} \\ &+ \Gamma_i(t') \tilde{\mathbf{a}}_i^\dagger(t') \tilde{\rho}(0) \Gamma_j(t'') \tilde{\mathbf{a}}_j^\dagger(t'') + \text{h.c.} \end{aligned} \right) \end{aligned} \right] \right\} \quad (7)$$

where

$$\Gamma_i(t) = \sum_k e^{-i\omega_k t} \alpha_{ik}^* \mathbf{c}_k, \quad \tilde{\mathbf{a}}_i(t) = e^{-i\omega_i t} \mathbf{a}_i, \quad (8)$$

and h.c. stands for Hermitian conjugate.

If at $t = 0$ the system is prepared in state $\rho_S(0)$ and the environment is admitted to be in thermal equilibrium,

$$\rho(0) = \rho_S(0) \otimes \rho_E(0) = \tilde{\rho}(0), \quad (9)$$

where

$$\begin{aligned} \rho_E(0) &= \frac{1}{Z} \prod_k \exp(-\beta \hbar \omega_k \mathbf{c}_k^\dagger \mathbf{c}_k) = \prod_k \left(\frac{1}{1 + \bar{n}_k} \right) \left(\frac{\bar{n}_k}{1 + \bar{n}_k} \right)^{\mathbf{c}_k^\dagger \mathbf{c}_k}, \\ Z &= \prod_k \sum_{n=0}^{\infty} \exp(-\beta \hbar \omega_k n), \quad \bar{n}_k = \frac{1}{\exp(\beta \hbar \omega_k) - 1}, \end{aligned} \quad (10)$$

$\beta = (k_B T)^{-1}$, k_B is Boltzmann constant, T the absolute temperature, Z the partition function and $\bar{n}_k$ the mean number of excitations of frequency ω_k [12]. Taking the limit of zero temperature, it is easy to see that

$$\begin{aligned} \tilde{\rho}_S(t) - \tilde{\rho}_S(0) &= \sum_{i,j=1}^2 \int_0^t dt' \int_0^{t'} d\tau \left\{ \left(\sum_k \alpha_{ik} \alpha_{jk}^* e^{i\omega_k \tau} \right) e^{-i\omega_j \tau} e^{i(\omega_j - \omega_i)t'} \left(\mathbf{a}_i \tilde{\rho}_S(0) \mathbf{a}_j^\dagger - \tilde{\rho}_S(0) \mathbf{a}_j^\dagger \mathbf{a}_i \right) \right\} \\ &\quad + \text{h.c.}, \end{aligned} \quad (11)$$

We used Fock states basis to take the traces over the environment and used for the integrals $\tau = t' - t''$.

Notice that $\sum_k \alpha_{ik} \alpha_{jk}^* e^{i\omega_k \tau}$ decays very fast when τ grows. Considering a huge number of environment modes, with frequencies spread over a large interval of values and a weak coupling to each mode (small α_{ik}), the phases of the $e^{i\omega_k \tau}$ make the sums practically null when τ is not close to zero. If τ_c is the time when $\sum_k \alpha_{ik} \alpha_{jk}^* e^{i\omega_k \tau}$ have appreciable values, we can, for $t \gg \tau_c$, modify the integration limits without changing substantially the result. Thus we obtain

$$\tilde{\rho}_S(t) - \tilde{\rho}_S(0) = \sum_{i,j=1}^2 \left\{ (k_{ij} + i\Delta_{ij}) \left(\mathbf{a}_i \tilde{\rho}_S(0) \mathbf{a}_j^\dagger - \tilde{\rho}_S(0) \mathbf{a}_j^\dagger \mathbf{a}_i \right) \left(\int_0^t dt' e^{i(\omega_j - \omega_i)t'} \right) \right\} + \text{h.c.}, \quad (12)$$

where the real numbers k_{ij} and Δ_{ij} are given by

$$k_{ij} + i\Delta_{ij} = \sum_k \alpha_{ik} \alpha_{jk}^* \int_0^{\tau_c} d\tau e^{i(\omega_k - \omega_j)\tau}. \quad (13)$$

Differentiating both sides of eq. (12) and iterating leads to

$$\frac{d}{dt} \tilde{\rho}_S(t) = \sum_{i,j=1}^2 \left\{ (k_{ij} + i\Delta_{ij}) \left(\mathbf{a}_i \tilde{\rho}_S(t) \mathbf{a}_j^\dagger - \tilde{\rho}_S(t) \mathbf{a}_j^\dagger \mathbf{a}_i \right) e^{i(\omega_j - \omega_i)t} \right\} + \text{h.c.} + \mathcal{O}^2(k_{ij} + i\Delta_{ij}) \quad (14)$$

The terms $\mathcal{O}^2(k_{ij} + i\Delta_{ij})$ are similar to the ones that appear if we consider $\mathcal{O}^4(\tilde{H}_{int})$ terms. Since we disregard $\mathcal{O}^3(\tilde{H}_{int})$, we will not take them in to account.

With the help of

$$\frac{d}{dt} \tilde{\rho}_S(t) = e^{\frac{i}{\hbar} \mathbf{H}_S t} \left\{ \frac{i}{\hbar} [\mathbf{H}_S, \rho_S(t)] + \frac{d}{dt} \rho_S(t) \right\} e^{-\frac{i}{\hbar} \mathbf{H}_S t} \quad (15)$$

we return to Schrödinger picture and write the master equation

$$\frac{d}{dt} \rho_S(t) = \mathcal{L} \rho_S(t), \quad (16)$$

where the Liouvillian superoperator (*i.e.*: operator which acts on operators) can be decomposed in three parts,

$$\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2 + \mathcal{L}_{12}, \quad (17)$$

and the parts are given by

$$\begin{aligned}
\mathcal{L}_1 &= k_{11} \left(2\mathbf{a}_1 \bullet \mathbf{a}_1^\dagger - \bullet \mathbf{a}_1^\dagger \mathbf{a}_1 - \mathbf{a}_1^\dagger \mathbf{a}_1 \bullet \right) + i \left(\Delta_{11} - \omega_1 \right) \left[\mathbf{a}_1^\dagger \mathbf{a}_1, \bullet \right] \\
\mathcal{L}_2 &= k_{22} \left(2\mathbf{a}_2 \bullet \mathbf{a}_2^\dagger - \bullet \mathbf{a}_2^\dagger \mathbf{a}_2 - \mathbf{a}_2^\dagger \mathbf{a}_2 \bullet \right) + i \left(\Delta_{22} - \omega_2 \right) \left[\mathbf{a}_2^\dagger \mathbf{a}_2, \bullet \right] \\
\mathcal{L}_{12} &= k_{12} \left(\mathbf{a}_1 \bullet \mathbf{a}_2^\dagger + \mathbf{a}_2 \bullet \mathbf{a}_1^\dagger - \bullet \mathbf{a}_2^\dagger \mathbf{a}_1 - \mathbf{a}_1^\dagger \mathbf{a}_2 \bullet \right) + \\
&\quad k_{21} \left(\mathbf{a}_2 \bullet \mathbf{a}_1^\dagger + \mathbf{a}_1 \bullet \mathbf{a}_2^\dagger - \bullet \mathbf{a}_1^\dagger \mathbf{a}_2 - \mathbf{a}_2^\dagger \mathbf{a}_1 \bullet \right) + \\
&\quad i \left(\frac{\Delta_{12} - \Delta_{21}}{2} \right) \left(\mathbf{a}_1 \bullet \mathbf{a}_2^\dagger - \mathbf{a}_2 \bullet \mathbf{a}_1^\dagger - \bullet \mathbf{a}_2^\dagger \mathbf{a}_1 + \mathbf{a}_1^\dagger \mathbf{a}_2 \bullet \right) + \\
&\quad i \left(\frac{\Delta_{21} - \Delta_{12}}{2} \right) \left(\mathbf{a}_2 \bullet \mathbf{a}_1^\dagger - \mathbf{a}_1 \bullet \mathbf{a}_2^\dagger - \bullet \mathbf{a}_1^\dagger \mathbf{a}_2 + \mathbf{a}_2^\dagger \mathbf{a}_1 \bullet \right) + \\
&\quad i \left(\frac{\Delta_{12} + \Delta_{21}}{2} \right) \left[\mathbf{a}_1^\dagger \mathbf{a}_2 + \mathbf{a}_2^\dagger \mathbf{a}_1, \bullet \right]. \tag{18}
\end{aligned}$$

A word about notation is in order: we use the conventional notation for superoperators [13] where the dot ($\bullet$) indicates the place to be occupied by the operator on which the superoperator is acting.

Now we consider the environment large enough to take the limit of dense spectrum. In this sense we define a density of modes $D(\omega)$ for the environment, where $D(\omega) d\omega$ represents the number of modes in the frequency interval between ω and $\omega + d\omega$. This allows the conversion of sums over modes ($\sum_k$) into integrals over frequencies ($\int D(\omega) d\omega$), with the corresponding change of α_k for $\alpha(\omega)$ and β_k for $\beta(\omega)$, leading to

$$\begin{aligned}
k_{ij} + i\Delta_{ij} &= \int d\omega D(\omega) \alpha_i(\omega) \alpha_j^*(\omega) \xi_j, \\
\xi_j &= \int_0^{\tau_c} d\tau e^{i(\omega - \omega_j)\tau}. \tag{19}
\end{aligned}$$

Using eqs. (3) we may write $\mathcal{L}$ in terms of the operators related to the original laboratory modes A and B :

$$\begin{aligned}
\mathcal{L} &= \mathcal{L}_A + \mathcal{L}_B + \mathcal{L}_{int}, \\
\mathcal{L}_A &= k_{aa} \left(2\mathbf{a} \bullet \mathbf{a}^\dagger - \bullet \mathbf{a}^\dagger \mathbf{a} - \mathbf{a}^\dagger \mathbf{a} \bullet \right) + i \left(\Delta_{aa} - \omega_a \right) \left[\mathbf{a}^\dagger \mathbf{a}, \bullet \right] \\
\mathcal{L}_B &= k_{bb} \left(2\mathbf{b} \bullet \mathbf{b}^\dagger - \bullet \mathbf{b}^\dagger \mathbf{b} - \mathbf{b}^\dagger \mathbf{b} \bullet \right) + i \left(\Delta_{bb} - \omega_b \right) \left[\mathbf{b}^\dagger \mathbf{b}, \bullet \right] \\
\mathcal{L}_{int} &= k_{ab} \left(\mathbf{a} \bullet \mathbf{b}^\dagger + \mathbf{b} \bullet \mathbf{a}^\dagger - \bullet \mathbf{b}^\dagger \mathbf{a} - \mathbf{a}^\dagger \mathbf{b} \bullet \right) + \\
&\quad k_{ba} \left(\mathbf{b} \bullet \mathbf{a}^\dagger + \mathbf{a} \bullet \mathbf{b}^\dagger - \bullet \mathbf{a}^\dagger \mathbf{b} - \mathbf{b}^\dagger \mathbf{a} \bullet \right) + \\
&\quad i \left(\frac{\Delta_{ab} - \Delta_{ba}}{2} \right) \left(\mathbf{a} \bullet \mathbf{b}^\dagger - \mathbf{b} \bullet \mathbf{a}^\dagger - \bullet \mathbf{b}^\dagger \mathbf{a} + \mathbf{a}^\dagger \mathbf{b} \bullet \right) + \\
&\quad i \left(\frac{\Delta_{ba} - \Delta_{ab}}{2} \right) \left(\mathbf{b} \bullet \mathbf{a}^\dagger - \mathbf{a} \bullet \mathbf{b}^\dagger - \bullet \mathbf{a}^\dagger \mathbf{b} + \mathbf{b}^\dagger \mathbf{a} \bullet \right) +
\end{aligned}$$

$$i \left(\left(\frac{\Delta_{ab} + \Delta_{ba}}{2} \right) - g \right) [\mathbf{b}^\dagger \mathbf{a} + \mathbf{a}^\dagger \mathbf{b}, \bullet]. \quad (20)$$

Here the coefficients are

$$k_{aa} + i\Delta_{aa} = \int d\omega D(\omega) \{ \alpha(\omega) \alpha^*(\omega) \eta + \alpha(\omega) \beta^*(\omega) \nu \}, \quad (21)$$

$$k_{ab} + i\Delta_{ab} = \int d\omega D(\omega) \{ \alpha(\omega) \alpha^*(\omega) \nu + \alpha(\omega) \beta^*(\omega) \mu \}, \quad (22)$$

$$k_{ba} + i\Delta_{ba} = \int d\omega D(\omega) \{ \beta(\omega) \alpha^*(\omega) \eta + \beta(\omega) \beta^*(\omega) \nu \}, \quad (23)$$

$$k_{bb} + i\Delta_{bb} = \int d\omega D(\omega) \{ \beta(\omega) \alpha^*(\omega) \nu + \beta(\omega) \beta^*(\omega) \mu \}, \quad (24)$$

$$\eta = \xi_1 \cos^2 \theta + \xi_2 \sin^2 \theta, \quad \mu = \xi_2 \cos^2 \theta + \xi_1 \sin^2 \theta, \quad \nu = (\xi_1 - \xi_2) \sin \theta \cos \theta. \quad (25)$$

It is important to note that all superoperators appearing in eqs. (20) form a closed Lie algebra (see table 1).

$\mathcal{L}_A$ and $\mathcal{L}_B$ are formally similar to the Liouvillians of independent modes evolving subjected to environment and $\mathcal{L}_{int}$ has the form of an “interaction Liouvillian”. However the constants k_{aa} and Δ_{aa} appearing in $\mathcal{L}_A$ depend on the coupling constants to the environment modes of both modes, $\alpha(\omega)$ and $\beta(\omega)$ (and analogously for k_{bb} and Δ_{bb}). The $\alpha(\omega) \beta^*(\omega)$ and $\beta(\omega) \alpha^*(\omega)$ terms appearing in eqs. (21) and (24) are related to the return from the normal modes when we write $\mathcal{L}$ in terms of operators of the original laboratory modes. Notice that (eqs. (19)) k_{ii} and Δ_{ii} ($i = 1$ or 2) depend only on $|\alpha_i(\omega)|^2$. In fact, it is more natural to see the whole system through its normal modes, and not to look at each cavity mode. This is what the environment does: due to the form of ξ_1 and ξ_2 , the values of $\alpha(\omega)$, $\beta(\omega)$ and $D(\omega)$ that effectively contribute to the coefficients of eqs. (20) are the ones with frequencies around the normal modes frequencies ω_1 and ω_2 , and not around the original laboratory modes frequencies ω_a and ω_b .

The physical interpretation for the coefficients Δ_{xy} and k_{xy} ($x, y = a$ or b) is straightforward if $x = y$: Δ_{aa} and Δ_{bb} concern the system’s unitary evolution, changing the oscillation frequencies of the cavities (the Lamb shift); k_{aa} and k_{bb} are dissipation constants. For $x \neq y$ the coefficients are related to a communication channel between the cavities mediated by the environment, playing unitary and non unitary roles in the dynamics (notice that $k_{ab} + i\Delta_{ab}$ and $k_{ba} + i\Delta_{ba}$ are not necessarily equal nor complex conjugate). As will become clear in sections (3) and (5), the values of k_{ab} and k_{ba} are very important for decoherence control. In eqs. (22) and (23) we find terms with $\alpha(\omega) \beta^*(\omega)$ and $\beta(\omega) \alpha^*(\omega)$ which integrals tend to be null if the phases of $\alpha(\omega)$ and $\beta(\omega)$ are not correlated. It is probably the most common case for fields in cavities. We must emphasize that analogous situation were studied in refs. [14] and [15] where the authors discuss the problem of two electric dipoles interacting

with the vacuum of electromagnetic field. The situation is formally similar, just changing bosonic operators for spin operators. However, as the dipoles are the only possibility of coupling, that system naturally exhibit this phase relation, and one can show [16,17] that this system is equivalent to the dipoles only coupled to one dissipative field mode. In the case of cavities, although it is desirable the phase relation, even in the uncorrelated case k_{ab} and k_{ba} may have appreciable values if $\nu \neq 0$ (eq. (25)), which may be achievable if, for example, the density of modes around ω_1 have a different behavior than around ω_2 . It is another effect that appear when we write eq. (20), going back to the original laboratory modes. Since the environment here is composed mainly by phonons in the mirrors of the cavities and by electromagnetic modes in the space around the cavities, it is not impossible to manipulate the density of modes.

3 General solution

Before going over to specific examples, we present in detail the general solution of the master equation (20).

The master equation (20) can be solved using Witschel's technique [18] and the parameter derivation technique[19]. This technique allows one to determine coefficients δ_i such that the following identity is valid

$$e^{(\gamma_1 \mathbf{A}_1 + \gamma_2 \mathbf{A}_2 + \dots + \gamma_n \mathbf{A}_n)t} = e^{\delta_1(t) \mathbf{A}_1} e^{\delta_2(t) \mathbf{A}_2} \dots e^{\delta_n(t) \mathbf{A}_n} \quad (26)$$

where the $\mathbf{A}_i$'s are superoperators forming a closed Lie algebra and t is a parameter (in our case, time). The parameter derivation technique consists of the following procedure:

- (1) Derive both sides of eq. (26) with respect to t and get

$$\begin{aligned} \left(\sum_{i=1}^n \gamma_i \mathbf{A}_i \right) \exp \left(\sum_{i=1}^n \gamma_i \mathbf{A}_i t \right) &= \dot{\delta}_1(t) \mathbf{A}_1 \prod_{i=1}^n e^{\delta_i(t) \mathbf{A}_i} \\ &+ \dot{\delta}_2(t) e^{\delta_1(t) \mathbf{A}_1} \mathbf{A}_2 \prod_{i=2}^n e^{\delta_i(t) \mathbf{A}_i} \\ &+ \dots \\ &+ \dot{\delta}_n(t) \prod_{i=1}^{n-1} e^{\delta_i(t) \mathbf{A}_i} \mathbf{A}_n e^{\delta_n(t) \mathbf{A}_n}. \end{aligned} \quad (27)$$

- (2) Use the similarity transformation

$$e^{x\mathbf{B}} \mathbf{A} e^{-x\mathbf{B}} = e^{x[\mathbf{B}, \bullet]} \mathbf{A}, \quad (28)$$

and the linear independence of $\{\mathbf{A}_i\}$ in order to obtain differential equations for the parameters $\delta_i(t)$.

- (3) Solve the c -numbers differential equations and obtain the factorized evolution superoperator written in the right hand side of eq. (26).

As an example of step 2 above, let us take the second term in the r.h.s. of eq. (27)

$$\begin{aligned} e^{\delta_1(t)\mathbf{A}_1}\mathbf{A}_2 &= e^{\delta_1(t)\mathbf{A}_1}\mathbf{A}_2e^{-\delta_1(t)\mathbf{A}_1}e^{\delta_1(t)\mathbf{A}_1} \\ &= e^{\delta_1(t)[\mathbf{A}_1,\bullet]}\mathbf{A}_2e^{\delta_1(t)\mathbf{A}_1} \\ &\equiv F_2(\delta_1(t), \{\mathbf{A}_i\})e^{\delta_1(t)\mathbf{A}_1}. \end{aligned} \quad (29)$$

Analogously one can define a similar operation for all the other terms and define

$$F_3 \equiv F_3(\delta_1(t), \delta_2(t), \{\mathbf{A}_i\}), \dots, F_n \equiv F_n(\delta_1(t), \delta_2(t), \dots, \delta_{n-1}(t), \{\mathbf{A}_i\}), \quad (30)$$

and write

$$\left(\sum_{i=1}^n \gamma_i \mathbf{A}_i\right) \exp\left(\sum_{i=1}^n \gamma_i \mathbf{A}_i t\right) = \left(\dot{\delta}_1 \mathbf{A}_1 + \dot{\delta}_2 F_2 + \dots + \dot{\delta}_n F_n\right) \exp\left(\sum_{i=1}^n \gamma_i \mathbf{A}_i t\right) \quad (31)$$

or, equivalently,

$$\sum_{i=1}^n \gamma_i \mathbf{A}_i = \dot{\delta}_1 \mathbf{A}_1 + \dot{\delta}_2 F_2 + \dots + \dot{\delta}_n F_n. \quad (32)$$

Comparing coefficients of each $\mathbf{A}_i$ (due to linear independence) one then obtains a system of coupled differential equations for the δ_i 's.

In our case we have

$$\begin{aligned} \rho_S(t) &= e^{\mathcal{L}t} \rho_S(0) \\ &= e^{h_1(t)\mathbf{a}\bullet\mathbf{a}^\dagger} e^{h_2(t)\mathbf{b}\bullet\mathbf{b}^\dagger} e^{z_l(t)\mathbf{a}\bullet\mathbf{b}^\dagger} e^{z(t)\mathbf{b}\bullet\mathbf{a}^\dagger} e^{n_l(t)\bullet\mathbf{a}^\dagger\mathbf{b}} e^{n(t)\mathbf{b}^\dagger\mathbf{a}\bullet} \\ &\quad e^{m_2(t)\mathbf{b}^\dagger\mathbf{b}\bullet} e^{p_2(t)\bullet\mathbf{b}^\dagger\mathbf{b}} e^{m_1(t)\mathbf{a}^\dagger\mathbf{a}\bullet} e^{p_1(t)\bullet\mathbf{a}^\dagger\mathbf{a}} e^{q(t)\mathbf{a}^\dagger\mathbf{b}\bullet} e^{q_l(t)\bullet\mathbf{b}^\dagger\mathbf{a}} \rho_S(0). \end{aligned} \quad (33)$$

Using the method just described we get

$$\begin{aligned} -i\Omega_{aa} - k_{aa} &= \dot{m}_1(t) - n(t) \dot{q}(t) e^{m_1(t)-m_2(t)}, \\ -i\Omega_{bb} - k_{bb} &= \dot{m}_2(t) + n(t) \dot{q}(t) e^{m_1(t)-m_2(t)}, \end{aligned}$$

$$\begin{aligned}
& -i\Omega_{ab} - k_{ab} = \dot{q}(t) e^{m_1(t)-m_2(t)}, \\
& -i\Omega_{ba} - k_{ba} = \dot{n}(t) + n(t) (\dot{m}_1(t) - \dot{m}_2(t)) - n(t)^2 \dot{q}(t) e^{m_1(t)-m_2(t)}, \\
& +i\Omega_{aa} - k_{aa} = \dot{p}_1(t) - n_l(t) \dot{q}_l(t) e^{p_1(t)-p_2(t)}, \\
& +i\Omega_{bb} - k_{bb} = \dot{p}_2(t) + n_l(t) \dot{q}_l(t) e^{p_1(t)-p_2(t)}, \\
& +i\Omega_{ab} - k_{ab} = \dot{q}_l(t) e^{p_1(t)-p_2(t)}, \\
& +i\Omega_{ba} - k_{ba} = \dot{n}_l(t) + n_l(t) (\dot{p}_1(t) - \dot{p}_2(t)) - n_l(t)^2 \dot{q}_l(t) e^{p_1(t)-p_2(t)}, \\
& 2k_{aa} = z(t) (-i\Omega_{ba} - k_{ba}) \\
& \quad + z_l(t) (+i\Omega_{ba} - k_{ba}) + h_1(t) (-2k_{aa}) + \dot{h}_1(t), \\
& 2k_{bb} = z(t) (+i\Omega_{ab} - k_{ab}) \\
& \quad + z_l(t) (-i\Omega_{ab} - k_{ab}) + h_2(t) (-2k_{bb}) + \dot{h}_2(t), \\
& +i(\Omega_{ab} - \Omega_{ba}) + k_{ba} + k_{ab} = z(t) (+i\Omega_{aa} - i\Omega_{bb} - k_{aa} - k_{bb}) \\
& \quad + h_1(t) (-i\Omega_{ab} - k_{ab}) + h_2(t) (+i\Omega_{ba} - k_{ba}) + \dot{z}(t), \\
& +i(\Omega_{ba} - \Omega_{ab}) + k_{ab} + k_{ba} = z_l(t) (-i\Omega_{aa} + i\Omega_{bb} - k_{aa} - k_{bb}) \\
& \quad + h_1(t) (+i\Omega_{ab} - k_{ab}) + h_2(t) (-i\Omega_{ba} - k_{ba}) + \dot{z}_l(t) \quad (34)
\end{aligned}$$

where

$$\Omega_{aa} = \omega_a - \Delta_{aa}, \quad \Omega_{bb} = \omega_b - \Delta_{bb}, \quad \Omega_{ab} = g - \Delta_{ab}, \quad \Omega_{ba} = g - \Delta_{ba}. \quad (35)$$

The solution reads

$$\begin{aligned}
n(t) &= \frac{l_2(t)}{f_1(t)}, \quad q(t) = \frac{l_1(t)}{f_1(t)}, \\
e^{m_1(t)} &= e^{-Rt} f_1(t), \quad e^{m_2(t)} = e^{-2Rt} e^{-m_1(t)}, \\
h_1(t) &= \frac{|f_2(t)|^2 + |l_2(t)|^2}{e^{-2k_m t}} - 1, \\
h_2(t) &= \frac{|f_1(t)|^2 + |l_1(t)|^2}{e^{-2k_m t}} - 1, \\
z(t) &= \frac{-l_1(t) f_2^*(t) - l_2^*(t) f_1(t)}{e^{-2k_m t}}, \\
z_l(t) &= z^*(t), \\
n_l(t) &= (n(t))^*, \quad q_l(t) = (q(t))^*, \\
p_2(t) &= (m_2(t))^*, \quad p_1(t) = (m_1(t))^*, \quad (36)
\end{aligned}$$

where

$$\begin{aligned}
f_1(t) &= \frac{1}{2r} [(r+c)e^{rt} + (r-c)e^{-rt}], \\
f_2(t) &= \frac{1}{2r} [(r-c)e^{rt} + (r+c)e^{-rt}],
\end{aligned}$$

$$\begin{aligned}
l_1(t) &= \frac{1}{2r} (i\Omega_{ab} + k_{ab}) (e^{-rt} - e^{rt}), \\
l_2(t) &= \frac{1}{2r} (i\Omega_{ba} + k_{ba}) (e^{-rt} - e^{rt}),
\end{aligned} \tag{37}$$

and

$$\begin{aligned}
c &= \frac{k_{bb} - k_{aa}}{2} + i \frac{(\Omega_{bb} - \Omega_{aa})}{2}, \\
r &= \sqrt{c^2 + (i\Omega_{ba} + k_{ba})(i\Omega_{ab} + k_{ab})}, \\
R &= \frac{k_{bb} + k_{aa}}{2} + i \frac{\Omega_{aa} + \Omega_{bb}}{2} = k_m + i\omega_m.
\end{aligned} \tag{38}$$

The above equations look complicated. However there are some ingredients in them which become very illuminating from the physical point of view. Let us then discuss a few of them in a general context and apply the results in specific situations in the next two sections.

It is probably sufficient to discuss the equation

$$e^{m_1(t)} = \frac{1}{2r} e^{-Rt} \left[(r + c) e^{rt} + (r - c) e^{-rt} \right], \tag{39}$$

since it carries the essential ingredients of dynamical evolution. The point we want to stress is that by controlling some parameters, one can have distinct regimes of dissipation and decoherence in this model. The factor e^{-Rt} in eq. (39) gives the expected decay behavior, with the average dissipation rate k_m . The term e^{-rt} contains two contributions: a term which measures to which degree the two cavities are different, c , which adds to the other term coming from the dynamical coupling of the modes through the environment ($k_{ab} - i\Delta_{ab}$ and $k_{ba} - i\Delta_{ba}$) and directly, *i.e.*: “through an antenna”, (ig). One interesting effect is that for some parameter choices, this e^{rt} term can cancel the deleterious effects of the overall factor e^{-Rt} . For example, take $\Omega_{aa} = \Omega_{bb}$ and $g = 0$, *i.e.*: two degenerated modes. Note that if $(k_{ab} - i\Delta_{ab})(k_{ba} - i\Delta_{ba}) = k_{aa}k_{bb}$, we get $r = k_m$, and, in this term, dissipation can be partially suppressed. Decoherence control is a little more intrincated matter, since it also depends on initial states as well. This will be discussed shortly.

4 Two weakly coupled cavities with initial coherent states: manipulating dissipation

In order to analyze specific cases, let us start with the simple situation in which coherent states are initially fed into the cavities:

$$\rho_S(0) = |v_a\rangle \langle v_a| \otimes |v_b\rangle \langle v_b|. \quad (40)$$

Applying the results of the previous section we get for the time evolution of this state

$$\rho_S(t) = |v_a(t)\rangle \langle v_a(t)| \otimes |v_b(t)\rangle \langle v_b(t)|, \quad (41)$$

where

$$\begin{aligned} v_a(t) &= e^{-(k_m + i\omega_m)t} \{v_a f_1(t) + v_b l_1(t)\}, \\ v_b(t) &= e^{-(k_m + i\omega_m)t} \{v_a l_2(t) + v_b f_2(t)\}. \end{aligned} \quad (42)$$

The first point to stress is that the known result of dissipative zero temperature time evolution of coherent states linearly coupled to the environment gives coherent states [20] applies here. Another point is that the auxiliary functions f_i and l_i are oscillatory, generalizing the well known behavior of cosine and sine in simple cases like two identical isolated modes. Finally, as it should be, the symmetric character of the expressions: each mode fed the other with a strength depending on the coupling $i\Omega_{ab} + k_{ab}$ and $i\Omega_{ba} + k_{ba}$.

In order to gain further insight let us make some simplifying but realistic assumptions. Consider two modes in different cavities (A and B) with the same frequency, $\omega_a = \omega_b = \omega$. The cavities are distant in the scale of the wavelength of the relevant mode, what leads to uncorrelated $\alpha(\omega)$ and $\beta(\omega)$ (see section (6)) and then $\int D(\omega) \alpha(\omega) \beta^*(\omega) \xi_i = 0$ ($i = 1$ and 2). If we have also $D(\omega)$, $|\alpha(\omega)|$ and $|\beta(\omega)|$ slow varying around ω_1 and ω_2 , the lamb shifts will be negligible: $\Delta_{aa} = \Delta_{bb} = 0$. Consider now very different dissipation rates, $k_{bb} \gg k_{aa}$ (two geometrically identical cavities made of different materials, *e.g.*: one superconductor and the other metallic), and weak direct coupling in the sense $g \ll \Delta k$ ($\Delta k = k_{bb} - k_{aa}$). Small g implies $\omega_1 \simeq \omega_2 \simeq \omega$. Thus $\nu \simeq 0$ and, since we already have $\int D(\omega) \alpha(\omega) \beta^*(\omega) \xi_i = 0$, the coupling through the environment practically vanishes: $k_{ab} - i\Delta_{ab} = k_{ba} - i\Delta_{ba} = 0$. These conditions lead to

$$\frac{c}{r} = \frac{\Delta k}{\sqrt{\Delta k^2 - 4g}} \approx 1 + \frac{2g^2}{\Delta k^2}, \quad (43)$$

and consequently to

$$\begin{aligned} v_a(t) &= e^{-i\omega_m t} \left\{ e^{-k_+ t} v_a + \frac{ig}{\Delta k} (e^{-k_- t} - e^{-k_+ t}) v_b \right\}, \\ v_b(t) &= e^{-i\omega_m t} \left\{ e^{-k_- t} v_b + \frac{ig}{\Delta k} (e^{-k_- t} - e^{-k_+ t}) v_a \right\}, \end{aligned} \quad (44)$$

where

$$\begin{aligned} k_+ &= k_{aa} + \frac{g^2}{\Delta k}, \\ k_- &= k_{bb} - \frac{g^2}{\Delta k}. \end{aligned} \quad (45)$$

The natural decay rate for cavity A (B) is approximately k_{aa} (k_{bb}). Under the assumption we made ($k_{bb} \gg k_{aa}$), if they were uncoupled cavity B mode would decay much faster than cavity A . The effect of the coupling is to alter the decay rate of both cavities, leaving in cavity B a component (which can be made large by controlling v_a) which will decay with approximately the rate of cavity A . This result resembles the classical situation of pendulum synchronization, in which the center of mass motion is superdamped and the worst pendulum becomes phase locked to the best one.

5 Superposition states: controlling coherence

We next model a feasible experimental situation where one constructs entangled states between two cavities [4]. We consider an initially pure entangled state

$$|\psi(0)\rangle = N^{\frac{1}{2}} (|w, 0\rangle - |0, w\rangle), \quad (46)$$

where w is an index for coherent state, $N = (2 - 2 \exp(-|w|^2))^{-1}$ and clearly the density operator is

$$\rho(0) = |\psi(0)\rangle \langle \psi(0)|.$$

The time evolution here is given by

$$\begin{aligned} \rho(t) &= N \left\{ \left(|\sigma_1(t), \epsilon_2(t)\rangle - e^{i\phi} |\epsilon_1(t), \sigma_2(t)\rangle \right) \left(\langle \sigma_1(t), \epsilon_2(t)| - e^{-i\phi} \langle \epsilon_1(t), \sigma_2(t)| \right) - \right. \\ &\quad \left[\left(\frac{|\langle 0|w\rangle|^2 - |\langle \epsilon_1(t)|\sigma_1(t)\rangle \langle \epsilon_2(t)|\sigma_2(t)\rangle| e^{-i\phi}}{\langle \epsilon_1(t)|\sigma_1(t)\rangle \langle \epsilon_2(t)|\sigma_2(t)\rangle} \right) |\sigma_1(t)\rangle \langle \epsilon_1(t)| \otimes |\epsilon_2(t)\rangle \langle \sigma_2(t)| + \text{h.c.} \right] \Big\} \end{aligned} \quad (47)$$

where

$$\begin{aligned}
\sigma_1(t) &= e^{-k_m t} e^{-i\omega_m t} f_1(t) w, \\
\sigma_2(t) &= e^{-k_m t} e^{-i\omega_m t} f_2(t) w, \\
\epsilon_1(t) &= e^{-k_m t} e^{-i\omega_m t} l_1(t) w, \\
\epsilon_2(t) &= e^{-k_m t} e^{-i\omega_m t} l_2(t) w
\end{aligned} \tag{48}$$

are also indices for coherent states. Note that the dynamics of the non-diagonal elements is dictated by the difference between the “distances” between the components of the initial state, $|\langle 0|w\rangle|^2$, and a similar quantity for the “time evolved” states in both cavities. The condition for coherence preservation is that

$$|\langle 0|w\rangle|^2 = \langle \epsilon_1(t) | \sigma_1(t) \rangle \langle \sigma_2(t) | \epsilon_2(t) \rangle, \tag{49}$$

i.e.: there is time evolution, but it is such that the scalar product of the evolved states is preserved. An extreme case would be unitary evolution, but we enforce that we only need this “unitary-like behavior” with respect to the vector states evolved in the initial state (46).

A simple way to study state’s purity is its linear entropy

$$\delta(\rho) = \text{Tr} \{ \rho - \rho^2 \}. \tag{50}$$

For the state of eq. (47) one gets

$$\delta(t) = \frac{(y^2(t) - 1)(x^2 - y^2(t))}{2y^2(t)(1 - x)^2}, \tag{51}$$

where $x = |\langle 0|w\rangle|^2$ and $y(t) = |\langle \epsilon_1(t) | \sigma_1(t) \rangle| |\langle \sigma_2(t) | \epsilon_2(t) \rangle|$. This latter quantity generalizes the well known result that the time scale of coherence loss in a single cavity depends on the “distance” of the states which constitute the initial superposition. Time dependent “distances” such as $|\langle \epsilon_i(t) | \sigma_i(t) \rangle|^2$ appear in the analytical expression for $\delta(t)$. Note that $\delta(t) = 0$ can be obtained by setting $k_{aa} = k_{bb} = k_{ab} = k_{ba}$, $\omega_a = \omega_b$ and $\Delta_{aa} = \Delta_{bb} = \Delta_{ab} = \Delta_{ba} = 0$.

6 Experimental (im)possibilities

It is clear that any “unexpected” result in the problem of two modes interacting with one reservoir comes from the cross terms k_{ab} , k_{ba} , Δ_{ab} and Δ_{ba} .

In fact, as usual in quantum mechanics, one is dealing with an interference phenomena. In ordinary two ways interference phenomena (*e.g.*: double slit), in order to achieve large visibility, one tries to balance the interferometer and to guarantee coherence between the two ways. Here, the interference is due to dissipation rates. Balance means that each reservoir mode interacts with both oscillators with the same strength. In a two ways interferometer, coherence means a fixed phase relation between the two ways. The same situation applies to coupling constants here: complete “coherence” (we will use “coherence” whenever we use the word coherence with this meaning; there must be no confusion with the term decoherence) is achieved only when the phase of $\frac{\alpha_k}{\beta_k}$ is independent of k . When the modes are directly coupled ($g \neq 0$), another effect can also originate cross terms, associated *e.g.* to variations of the density of modes between the two normal modes frequencies [21].

We begin by considering two field modes of distinct cavities. In principle, the reservoir contains modes of all frequencies. It is not bad to consider that the large wavelength modes interact with both cavities’ modes in a “coherent” way (something similar to the dipole approximation [22]). However, the modes close to resonance are potentially the most important ones, as is emphasized by eq. (13). If on top of that the most important reservoir modes are also field modes, this means that the most important wavelengths are close to the wavelength of the cavities’ modes. This suggests difficulties to implement this situation with distant cavities in the mode wavelength scale. Finally, the short wavelength modes of the reservoir, even without very large contributions to individual decay processes, generally will tend to destroy this “coherence” condition. As long as no directly coupling is imposed, one doesn’t need to consider other effects.

The above argumentation suggests the use of two modes of one and the same cavity. Now, if one thinks in terms of wavelengths, the most important reservoir modes may possibly interact with the cavity modes in a “coherent” way. However, two (almost) degenerated modes form a two level system, and one can think about them as two polarizations of one spatial mode. The “coherent” interaction with the reservoir then defines a superdamped and a subdamped polarizations, in a way similar to super and subradiant modes of an n atoms maser [23], and in the limit situation, the subdamped mode would become a decoherence (and dissipation) free subspace (or mode). But what if we change our description from the previous polarizations to the super and subdamped ones? Then we would be describing a system where only one polarization is coupled to the reservoir, while the other is (almost) free. This is not the case, in general, but it is the case for some systems. One good example is the experiment of ref. [24], where DFS principle is addressed. A classical analog is given by two coupled harmonic oscillators, where center of mass mode usually couples strength with the environment and decays (much) faster then the relative motion. Another favorable situation is the dipole situation [14,15] where

one has a first principles model for the coupling constants, and “coherence” can be naturally achieved manipulating the dipoles.

Obviously an explicit mechanism regarding the geometry of the cavities is still missing. It will be introduced and compared to experiment in a forthcoming publication [25].

In short, we studied the effects of correlations among coupling constants of each of two modes with a common reservoir, showing that they can smoothly vary from two independent damped systems, to one overdamped and one free modes, in case of perfect correlations and/or ubiquitous environment density of modes. Examples of state evolution were given and some experimental considerations were made, and we believe that some light was shed on decoherence and dissipation processes for composed systems in cavity QED when the proposed decoherence mechanism seems to work well [11].

Table 1

Commutation relations $[\chi_i, \chi_j]$ for the bosonic superoperators (χ_i and χ_j are given by the line and the column respectively).
